*** **Creating and manipulating layers** :**
Understanding layers and using multiple layers that you can resize and position is essential for Photoshop mastery. A `_layer_` is an individual object or path in a drawing. When you create a new document in Photoshop, it opens on a single layer. You can add more layers by clicking the Layer button and dropping a new layer on the background (often called the `_canvas_`). You can move, rotate, and resize layers. You can move a layer so that it is on top of or behind the others, but it retains transparency. You can toggle the visibility of layers by selecting it, Ctrl-clicking it (Windows) or Option-clicking it (Mac OS), and then clicking the Visibility icon in the Layers panel, shown in

Figure 6-1. Layer visibility lets you use a layer without having to know how the others are organized. When you select a layer, the Layers panel displays the Layers panel options shown in Figure 6-1. In the Layers panel, the first three buttons at the top of the panel do the following: * **View** * : Changes the layer's appearance. The first option at the top (i.e., the default setting) is called Normal. It looks like what you see in the Background (Image) panel at the top of Figure 6-1. * **Duplicate** * : Stands for "duplicate layer." It duplicates the layer on the same canvas with a copy next to the original. A copy doesn't move with the original, and its colors are based on the original layer. Duplicating a layer opens a dialog box that lets you name the copy (Figure 6-2, left). FIGURE 6-1 FIGURE 6-2

Left: The Duplicate dialog box lets you name the new layer and change its size and color.

Right: You can apply the duplicate layer to any existing layer or path or to the background. If you drag in the Properties inspector, the highlighted color for the new duplicate layer turns blue (Figure 6-2, right).

Click OK to close the box and close the Duplicate dialog. * **Merge Visible

Layers** : This option is on by default. When you select it, Photoshop merges the layers that are visible. You can merge layers only when working in the Photoshop Layers panel, so if you create

Hyperparathyroidism complicating acute kidney injury: role of serum calcium, phosphorus, calcitriol, and parathyroid hormone. Acute kidney injury (AKI) has been associated with hyperparathyroidism in animal studies. To characterize the

association between AKI and hyperparathyroidism in humans, we performed a retrospective review of the serum calcium, phosphorus, calcitriol, and parathyroid hormone concentrations in patients with acute kidney injury requiring dialysis. Our hypothesis was that an abnormal ratio of serum calcium to phosphorus (Ca/P) would be associated with the development of AKI and hyperparathyroidism in this critically ill patient population. All patients were adult patients admitted to an intensive care unit between January 1, 2010 and April 30, 2012 with a need for renal replacement therapy. Serum calcium, phosphorus, intact parathyroid hormone, and calcitriol levels were collected within 48 hours before and 48 hours after initiation of renal replacement therapy. We enrolled 21 patients during the

study period, and of the 21 patients, 12 (57%) developed AKI, with hypercalcemia occurring in all patients (11 [52%]) and hyperphosphatemia in 8 (38%), all of whom had a serum Ca/P ratio greater than 1.3, the cutoff for abnormal. In addition, 4 (19%) developed hyperparathyroidism with a high serum intact parathyroid hormone level, all of whom had a serum Ca/P ratio greater than 1.3. Hypercalcemia, hyperphosphatemia, and hyperparathyroidism were associated with AKI.

Nitrifier and bacterial diversity in a pilot-scale UASB-A system treating slaughterhouse wastewater supplemented with organic loading. The diversity of nitrifying microorganisms and the changes in their relative abundance in batch experiments with anaerobic sludge taken from a full-scale anaerobic digester treating slaughterhouse

wastewater supplemented with organic loading were determined. The sludge was fed with synthetic wastewater supplemented with ammonium at a concentration of 5 mg N/L as $\text{NH}_4(+)\text{-N}$ and lactose at a concentration of 10 mg COD/L as COD. Sludge was inoculated to various concentrations of organic matter and this was fed for two weeks to study the effect of high organic loading. The ammonia-oxidizing archaea (AOA) were the most abundant bacterial group at the start of the experiment. The dominance of AOA decreased with increasing
